Dispatching Requests

- [Main process](#)
- [Include/Forward](#)
- [Included Request Attributes](#)

Main process

The following steps should give you an overview how a request is processed in Sling. Details can be found under provided links.

1. The client sends the request
2. This step applies only if a Servlet Container is installed and Sling is embedded: Servlet Container gets request and forwards to OSGi HttpService
3. OSGi HttpService looks for responsible registered Servlet or resource (see 102.4 of the OSGi compendium)
4. OSGi HttpService calls `handleSecurity` of the `HttpContext` associated with the servlet/resource. In case of Sling this calls into `SlingMainServlet.handleSecurity` and then into `SlingAuthenticator.authenticate`
 1. `SlingAuthenticator` selects an authentication handler for the request and forwards the authenticate call. On success a `javax.jcr.Session` is created, the request attributes required by the HTTP Service spec are set (like `org.osgi.service.http.authentication.remote.user` and `org.osgi.service.http.authentication.type` and also the `javax.jcr.Session` which is used later is set in the request attributes. On success, continue with step 5.
 2. If authentication fails either an anonymous session is acquired (if anonymous is allowed per configuration) or the login method is called. If anonymous is allowed, continue with step 5.
 3. The login method selects an `AuthenticationHandler` and forwards the login call to the `AuthenticationHandler.requestAuthentication` method to cause the client to authenticate. Request processing stops here (`SlingMainServlet.handleSecurity` returns false).
5. After getting a response the `HttpService` either terminates the request (if authentication failed and `SlingMainServlet.handleSecurity` returned false) or continues by either spooling the resource or in the case of Sling calling the `SlingMainServlet.service` method.
6. The `SlingMainServlet.service` method is the entry point into the Sling proper. This method sets up the request:
 - Wraps the `HttpServletRequest` and the `HttpServletResponse` into the `SlingHttpServletRequest` and the `SlingHttpServletResponse`
 - Checks if Sling is ready for processing the request (checks at the moment for an existing `ResourceResolverFactory` service, a `ServletResolver` service and a `MimeTypeService`)
 - Create the `ResourceResolver` based on the `Session` (by default creates a `JcrResourceResolver2`)
 - Locate the [Resource](#) on the basis of the request by calling `ResourceResolver.resolve` through `RequestData.initResource` (see also [URL decomposition](#))
 - Locate the servlet or script (see [Servlets](#)) by calling `ServletResolver.resolveServlet` through `RequestData.initServlet`
7. After this setup, the request level filters are called (the ones registered as `javax.servlet.Filter` with the property `filter.scope=request`, see [Filters](#) for details). If any called filter doesn't call `FilterChain.doFilter` at the end of the `Filter.doFilter` method request processing stops here.
8. After having called all request level filters, the component level filters (registered with the property `filter.scope=component`, see [Filters](#) for details) are called.
9. After having called the component level filters, the request servlet or script is finally called to process the request.

Include/Forward

If a servlet or script is including another resource for processing through the `RequestDispatcher.include` or `RequestDispatcher.forward` (or any JSP or feature of another scripting language which relies on one of this two

methods) the following processing takes place:

1. Code in the processing servlet or script calls `RequestDispatcher.include` or `RequestDispatcher.forward`.
2. The resource is resolved through `ResourceResolver.getResource` (if the `RequestDispatcher` has not been created with a resource already)
3. The servlet or script to handle the resource is resolved calling the `ServletResolver.resolveServlet` method.
4. The component level filters (registered with the property `filter.scope=component`) are called again (see [Filters](#) for details).
5. The servlet or script is called to process the request.

Note that these steps are processed for every include or forward call.

Included Request Attributes

When servlet or script is called as a result of `RequestDispatcher.include` the following request attributes are set:

Attribute Name Attribute Type	Description
<code>org.apache.sling.api.include.servlet</code> <code>javax.servlet.Servlet</code>	The name of the request attribute containing the <code>Servlet</code> which included the servlet currently being active.
<code>org.apache.sling.api.include.resource</code> <code>org.apache.sling.api.resource.Resource</code>	The name of the request attribute containing the <code>Resource</code> underlying the <code>Servlet</code> which included the servlet currently being active.
<code>org.apache.sling.api.include.request_path_info</code> <code>org.apache.sling.api.request.RequestPathInfo</code>	The name of the request attribute containing the <code>RequestPathInfo</code> underlying the <code>Servlet</code> which included the servlet currently being active
<code>javax.servlet.include.request_uri</code> <code>String</code>	The name of the request attribute containing the <code>HttpServletRequest.getRequestURI()</code> of the request which included the servlet currently being active underlying the <code>Servlet</code> which included the servlet currently being active. Note: In Sling, the <code>HttpServletRequest.getRequestURI()</code> method will always return the same result regardless of whether it is called from the client request processing servlet or script or from an included servlet or script. This request attribute is set for compatibility with the Servlet API specification.
<code>javax.servlet.include.context_path</code> <code>String</code>	The name of the request attribute containing the <code>HttpServletRequest.getContextPath()</code> of the request which included the servlet currently being active underlying the <code>Servlet</code> which included the servlet currently being active. Note: In Sling, the <code>HttpServletRequest.getContextPath()</code> method will always return the same result regardless of whether it is called from the client request processing servlet or script or from an included servlet or script. This request attribute is set for compatibility with the Servlet API specification.
<code>javax.servlet.include.servlet_path</code> <code>String</code>	The name of the request attribute containing the <code>HttpServletRequest.getServletPath()</code> of the request which included the servlet currently being active underlying the <code>Servlet</code> which included the servlet currently being active. Note: In Sling, the <code>HttpServletRequest.getServletPath()</code> method will always return the same result regardless of whether it is called from the client request processing servlet or script or from an included servlet or script. This request attribute is set for compatibility with the Servlet API specification.
<code>javax.servlet.include.path_info</code> <code>String</code>	The name of the request attribute containing the <code>HttpServletRequest.getPathInfo()</code> of the request which included the servlet currently being active underlying the <code>Servlet</code> which included the servlet currently being active. Note: In Sling, the <code>HttpServletRequest.getPathInfo()</code> method will always return the same result regardless of whether it is called from the client request processing servlet or script or from an included servlet or script. This request attribute is set for compatibility with the Servlet API specification.
<code>javax.servlet.include.query_string</code> <code>String</code>	The name of the request attribute containing the <code>HttpServletRequest.getQueryString()</code> of the request which included the servlet currently being active underlying the <code>Servlet</code> which included the servlet currently being active. Note: In Sling, the <code>HttpServletRequest.getQueryString()</code> method will always return the same result regardless of whether

Attribute Name	Description
Attribute Type	it is called from the client request processing servlet or script or included servlet or script. This request attribute is set for compatibility with the Servlet API specification.

Constants are defined in the `org.apache.sling.api.SlingConstants` class for these request attributes.

Note: These request attributes are not set if the servlet or script is called to handle the request or as a result of `RequestDispatcher.forward`.
